Vorlesung 1

```
-- Hello World Haskell
main :: IO ()
main = putStrLn "Chewie, we're home"
```

Code example 1: Hello World

Functional Programming (FP)

A programming language is a medium for expressive ideas (not to get a computer to perform operations). Thus programs must be written for people to read, and only incidentally for machines.

Computational Model in FP: Reduction

Replace expressions by their value.

IN FP, expressions are formed by applying functions to values.

- 1. Function as in maths: $x = y \rightarrow f(x) = f(y)$
- 2. Functions are values like numbers or text

	FP	Imperative
construction	function application and composition	statement sequencing
execution	reduction (expression evaluation)	state changes
semantics	λ -calculus	denotational

 $n \in \mathbb{N}, n \ge 2$ is a prime number \Leftrightarrow the set of non-trivial factors of n is empty. n is prime $\Leftrightarrow \{m \mid m \in m \in \{2, \dots, n-1\}, nmod m = 0\} = \{\}$

```
int IsPrime(int n)
    int m;
    int found_factor;
    found factor
    for (m = 2; m \le n -1; m++)
        if (n \% m == 0)
            found_factor = 1 ;
            break;
        }
    }
    return !found factor;
}
                  Code example 2: isPrime in C
isPrime :: Integer -> Bool
isPrime n = factors n == []
  where
    factors :: Integer -> [Integer]
    factors n = [m \mid m < -[2..n-1], mod n m == 0]
main :: IO ()
main = do
  let n = 42
  print (isPrime n)
```

Code example 3: isPrime in Haskell

```
let xs = [ x+1 | x <- [0..9] ]
:sprint xs = _
length xs
:sprint xs = [_,_,_,_,_,_,_]</pre>
```

Code example 4: Lazy Evaluation in der ghci REPL

Haskell Ramp Up

```
Read \equiv as "denotes the same value as" Apply f to value e: f _{\square}e (juxtaposition, "apply", binary operator _{\square}, Haskell speak: infixL 10 _{\square}) = _{\square}has max precedence (10): f e_1 + e_2 \equiv (f e_1) + e_2 \equiv associates to the left g _{\square}f _{\square}e \equiv (g
```

f) e Function composition:

```
- g (f e)
```

```
- Operator "." ("after") : (g.f) e (. = \circ) = g(f (e))
```

- Alternative "apply" operator \$ (lowest precedence, associates to the right), infix 0\$): $f_{e_1} + e_2 = f(e_1 + e_2)$

Vorlesung 2

```
cos 2 * pi
cos (2 * pi)
cos $ 2 * pi
isLetter (head (reverse ("It's a " ++ "Trap")))
(isLetter . head . reverse ) ("It's a" ++ "Trap")
isLetter $ head $ reverse $ "It's a" ++ "Trap"
```

Code example 5: Verschiedene Schreibweise einer Applikation

Prefix application of binary infix operator \oplus

```
(\oplus)e_1e_2 \equiv e_1 \oplus e_2

(&&) True False \equiv False

Infix application of binary function f:

e_1 `f` e_2 \equiv f e_1e_2

x `elem` xs \equiv x \in xs

User defined operators with characters : !#%&*+/<=>?@\^ |

epsilon :: Double

epsilon = 0.00001

(\sim=\sim) :: Double -> Double -> Bool

x \sim=\sim y = abs (x - y) < epsilon

infix 4 \sim=\sim
```

Code example 6: Eigener \approx Opperator

Values and Types

```
Read:: as "has type"

Any Haskell value e has a type t (e::t) that is determined at compile time.

The:: type assignment is either given explicitly or inferred by the computer
```

Types

```
Type
              Description
                                                      Value
              fixed precision integers (-2^{63} \dots 2^{63} - 1)
                                                      0,1,42
Int
                                                      0,10^100
              arbitrary Precision integers
Integer
Float, Double
              Single/Double precision floating points
                                                      0.1, 1e03
                                                      'x','\t', '', '\8710'
Char
              Unicode Character
                                                      True, False
Bool
              Booleans
              Unit (single-value type)
()
                                                      ()
2
it :: Integer
42 :: Int
it :: Int
'a'
it :: Char
True
it :: Bool
10^100
it :: Integer
10^100 :: Double
it :: Double
```

Type Constructors

- Build new types from existing Types
- Let a,b denote arbitrary Types (type variables)

Type Constructor	Description	Values
(a,b)	pairs of values of types a and b	(1,True) :: (Int, Bool)
$(\mathbf{a}_1,\mathbf{a}_2,\ldots,\mathbf{a}_n)$	n-Types	2,False :: (Int, Bool)
[a]	list of values of type a	[] :: [a]
Maybe a	optional value of type a	Just 42 Maybe Integer
		Nothing :: Maybe a
Either a b	Choice between values of Type a and b	Left 'x' :: Either Char b
		Right pi :: Either a Double
IO a	I/O action that returns a value of type	print 42 :: IO ()
	a (can habe side effects)	
	•	getChar :: IO Char
a -> b	function from type a to b	isLetter :: Char -> Bool

```
(1, '1', 1.0)
it :: (Integer, Char, Double)
[1, '1', 1.0]
it :: Fehler
[0.1, 1.0, 0.01]
it :: [Double]
[]
it :: [t]
"Yoda"
it :: [Char]
['Y', 'o', 'd', 'a']
"Yoda"
[Just 0, Nothing, Just 2]
it :: [Maybe Integer]
[Left True, Right 'a']
it :: [Either Bool Char]
print 'x'
it :: ()
getChar
it :: Char
:t getChar
getChar :: Io Char
:t fst
fst :: (a,b) -> a
:t snd
snd :: (a,b) -> b
:t head
head :: [a] -> a
:t (++)
(++) :: [a] -> [a] -> [a]
```

Currying

• Recall:

```
1. e_1 + e_2 \equiv (++) e_1 e_2
2. ++ e_1 e_2 \equiv (++) e_1 e_2
```

- Function application happens one argument at a time (currying, Haskell B. Curry)
- Type of n-ary function: : $a_1 \rightarrow a_2 \dots \rightarrow a_n \rightarrow b$
- Type constructor -> associates to the right thus read the type as: $a_1 \rightarrow (a_2 \rightarrow a_3 (\dots \rightarrow (a_n \rightarrow b)...))$

• Enables partial application: "Give me a value of type a_1 , I'll give you a (n-1)-ary function of type $a_2 \rightarrow a_3 \rightarrow \dots \rightarrow a_n \rightarrow b$

```
"Chew" ++ "bacca"
"Chewbacca"
(++) "Chew" "bacca"
"Chewbacca"
((++) "Chew") "bacca"
"Chewbacca"
:t (++) "Chew"
"Chew" :: [Char] -> [Char]
let chew = (++) "Chew"
chew "bacca"
"Chewbacca"
let double (*) 2
double 21
42
```

Vorlesung 3

Defining Values (and thus: Functions)

- = binds names to values, names must not start with A-Z (Haskell style: camelCase)
- Define constant (0-ary) c, value of c is that of expression: c=e
- Define n-ary function, arguments x_i and f may occur in e (no "letrec" needed)

$$f x_1 x_2 \dots x_n = e$$

- Hskell programm = set of top-level bindings (order immaterial, no rebinding)
- Good style: give type assignment for top-level bindings:

• Guards (introduced by |).

• q_i (expressions of type Bool) evaluated top to bottom, first True guards "wins"

fac
$$n = \begin{cases} 1 & ifn \ge 1 \\ n \cdot fac(n-1) & else \end{cases}$$

```
fac :: Integer -> Integer
fac n = if n \le 1 then 1 else n * fac (n - 1)
fac2 n | n <= 1 = 1
       | otherwise = n * fac2 (n - 1)
main :: IO ()
main = print $ fac 10
                  Code example 7: fac in Haskell
power :: Double -> Integer -> Double
power x k \mid k == 1 = x
          \mid even k = power (x * x) (halve k)
          | otherwise = x * power (x * x) (halve k)
  where
    even :: Integer -> Bool -- Nicht typisch
    even n = n \mod 2 == 0
    halve n = n \cdot div \cdot 2
main :: IO ()
main = print $ power 2 16
```

Code example 8: Power in Haskell

Lokale Definitionen

1. where - binding : Local definitions visible in the entire right-hand-side (rhs) of a definition

```
\begin{array}{lll} \text{f} & x_1 & x_2 & \dots & x_n \\ & | \, q_1 & = \, e_1 \\ & | \, q_2 & = \, e_n \\ & \text{where} \\ & g_1 & \dots & = \, b_1 \\ & g_i & \dots & = \, b_i \end{array}
```

2. let - expression Local definitions visible inside an expression:

Haskells 2-dimensionale Syntax (Layout) (Forumbeitrag)

Hallo zusammen,

in der dritten Vorlesung hatte ich erwähnt, dass Haskells Syntax darauf verzichtet, Blöcke (von Definitionen) mittels Sonderzeichen abzugrenzen und zu strukturieren. Andere Programmiersprachen bedienen sich hier typischerweise Zeichen wie , und ;.

Haskell baut hingegen auf das sog. Layout, eine Art 2-dimensionaler Syntax. Wer schon einmal Python und seine Konventionen zur Einrückung von Blöcken hinter for und if kennengelernt hat, wird hier Parallelen sehen. Die Regelungen zu Layout lauten wie folgt und werden vom Haskell-Compiler während der Parsing-Phase angewandt:

- The first token after a where/let and the first token of a toplevel definition define the upper-left corner of a box.
- The first token left of the box closes the box (offside rule).
- Insert a { before the box.
- Insert a } after the box.
- Insert a; before each line that starts at left box border.

Die Anwendung dieser Regeln auf dieses Beispielprogramm:

führt zur Identifikation der folgenden Box:

let
$$\begin{vmatrix} y &= a * b \\ f x = (x + y) / y \end{vmatrix}$$

in
$$f c + f d$$

Das Token in in der letzten Zeile steht links von der Boxgrenze im Abseits (siehe die offside rule). Der Parser führt nun die Zeichen , und ; ein und verarbeitet das Programm so, als ob der Programmierer diese Zeichen explizit angegeben hätte. (Haskell kann alternativ übrigens auch in dieser sog. expliziten Syntax geschrieben werden — das ist aber sehr unüblich, hat negativen Einfluss aufs Karma und ist vor allem für den Einsatz in automatischen Programmgeneratoren gedacht.)

Die explizite Form des obigen Programmes lautet (nach den drei letzten Regeln):

```
let {y = a * b
;f x = (x + y) / y}
in f c + f d
```

Damit ist die Bedeutung des Programmes eindeutig und es ist klar, dass bspw. nicht das folgende gemeint war (in dieser alternativen Lesart ist das Token f aus der zweiten in die erste Zeile "gerutscht"):

```
let y = a * b f
 x = (x + y) / y
in f c + f d
```

Aus diesen Layout-Regeln ergeben sich recht einfache Richtlinien für das Einrücken in Haskell-Programmen:

- Die Zeilen einer Definition auf dem Top-Level beginnen jeweils ganz links (Spalte 1) im Quelltext.
- Lokale where / let-Definitionen werden um mindestens ein Whitespace (typisch: 2 oder 4 Spaces oder 1 Tab) eingerückt.
- Es gibt in Haskell ein weiteres Keyword (do, wird später thematisiert), das den gleichen Regeln wie where / let folgt.

Beste Grüße,

—Torsten Grust

Lists([a])

• Recursive definition:

```
    [] ist a list (nil), type [] :: [a]
    x : xs (head, tail) is a list, if x :: a, and xs :: [a].
    cons: (:) :: a -> [a] -> [a] with infixr : 5
```

• Notation: $3:(2:1:[]) \equiv 3:2:1:[] \equiv [3,2,1]$

```
[]
it :: [t]
[1]
it :: [Integer]
[1,2,3]
it :: [Integer]
['z']
" Z "
it :: [Char]
['Z','X']
"ZX"
it :: [Char]
[] == ""
True
it :: Bool
[[1],[2,3]]
it :: [[Integer]]
[[1],[2,3],[]]
[[1],[2,3]]
it :: [[Integer]]
False:[]
[False]
it :: [Bool]
(False:[]):[]
it ::[[Bool]]
:t [(<),(<=),(>)]
[(<),(<=),(>)] :: Ord a => [a -> a-> Bool]
[(1, "one"),(2, "two"),(3, "three")]
it :: [(Integer,[Char])]
:t head
head :: [a] -> a
:t tail :: [a] -> [a]
head "It's a trap"
ΊΙ'
it :: Char
tail "It's a trap"
"t's a trap"
it :: [Char]
reverse "Never odd or even"
"neve ro ddo reveN"
it :: [Char]
  • Law \forall xs \neq []: head xs : tail = xs
```

:i String

type String = [Char]

Type Synonyms

• Introduce your own type synonyms. (type names : Uppercase) type $t_1 = t_2$ type Bits = [Integer]

Sequence (lists of enumerable elements)

```
• [x..y] = [x,x+1,x+2,...,y]
['a'..'z']
"abcdefghijklmnopqrstuvwxyz"
```

```
• x,s..y \equiv [x,x+i,x+(2*i),...,y] where i = x-s [1,3..20] [1,3,5,7,9,11,13,15,17,19] [2,4..20] [2,4,6,8,10,12,14,16,18,20]
```

• Infinite List [1..]

Vorlesung 4

match.

Pattern Matching

```
The idiomatic way to define functions by cases: \mathbf{f}::a_1 \to a_k \to \mathbf{b} \mathbf{f} p_{11} \dots p_{1k} = e_1 \vdots : \vdots : \vdots \mathbf{f} p_{m1} \dots p_{nk} = e_n For all e_i :: \mathbf{b} on a_i call \mathbf{f} x_1 x_2 \dots x_k each x_i is matched against patterns p_{i1} \dots p_{in} in order. Result is e_r if the rth branch is the first in which all patterns
```

Pattern	Matches if	Bindings in e_r
constant c	$x_1 == c$	
variable v	always	$v = x_i$
${\rm wildcard} \ _$	always	
tuple (p_1,\ldots,p_n)	components of x_i match	Those bound by the com-
	type component patterns	ponent patterns
	$x_i == []$	
$p_1: p_2$	head x_1 matches p_1 ,	
	tail x_i matches p_2	
v@p	p matches	those bound by p and $v =$
		x_i
Note: In a pattern.	a variable may only occur on	ice (linear patterns only)

Note: In a pattern, a variable may only occur once (linear patterns only)

```
--(1) if then else
sum' :: [Integer] -> Integer
sum' xs =
  if xs == [] then 0 else head xs + sum' (tail xs)
--(2) guards
sum'' :: [Integer] -> Integer
sum'' xs | xs == [] = 0
   | otherwise = head xs + sum'' (tail xs)
--(3) pattern matching
sum''' :: [Integer] -> Integer
sum''' [] = 0
sum''' (x:xs) = x + sum''' xs
main :: IO ()
main = do
 print $ sum' [1,2,3]
 print $ sum'' [1,2,3]
  print $ sum''' [1,2,3]
```

Code example 9: sum in Haskell

Pattern matching in expressions (case)

```
case e of p_1 \mid q_{11} \rightarrow e_{11}
                     p_n \mid q_{n1} \rightarrow e_{n1}
```

Code example 10: ageOf in Haskell

```
take' :: Integer -> [a] -> [a]
take' 0 _ = []
take' _ [] = []
take' n (x:xs) = x:take' (n-1) xs

main :: IO ()
main = print $ take' 20 [1,3..]
```

Code example 11: take in Haskell

Code example 12: merge in Haskell

```
--Sortes a list
mergeSort :: (a -> a -> Bool) -> [a] -> [a]
                    = []
mergeSort _ []
mergeSort _
               [x]
                      = [x]
mergeSort (<<<) xs = merge (<<<) (mergeSort (<<<) ls)</pre>
                                 (mergeSort (<<<) rs)</pre>
  where
    (ls,rs) = splitAt (length xs `div` 2) xs
    merge :: (a -> a -> Bool) -> [a] -> [a] -> [a]
    merge _
                                     = ys
                    []
                               уs
                                    = xs
    merge
                               []
                    ΧS
    merge (<<<) 11@(x: xs) 12@(y:ys)
      | x <<< y = x:merge (<<<) xs 12
      | otherwise = y:merge (<<<) l1 ys
main :: IO ()
main = print $ mergeSort (<) [1..100]</pre>
```

Code example 13: mergeSort in Haskell

Vorlesung 5

Algebraic Data Types (Sum of Product Types)

- Recall: [] and (:) are the constructors for Type [a]
- Can define entirely new Type T and its constructors K_i :

```
data T a_1 a_2 \dots a_n = K_1 b11 \dots b_{1n_1} |K_2 b_{21} \dots b_{2n_2} \vdots \vdots |K_r b_{r1} \dots b_{rnr}
```

- Defines Type constructor T and r value constructor with types
- $K_i :: b_{i1} \dots b_{ini} \rightarrow Ta_1 a_2 \dots a_n$
- K_i identifier with uppercase first letter or symbol starting with:
- Example: [weekday.hs]
 - Sum (or enumeration, choice)

```
data Weekday = Mon | Tue | Wed | Thu | Fri | Sat | Sun
  deriving (Eq,Show,Ord,Enum,Bounded)
weekend :: Weekday -> Bool
weekend Sat = True
weekend Sun = True
weekend _ = False

main :: IO ()
main = do
  print $ weekend Mon
  print $ [Mon..Fri]
```

Code example 14: weekday.hs

```
Wed
No instance for (Show Weekday) arising from a use of print
Thu == Sun
No instance for (Eq Weekday) arising from a use of '=='
Mon > Sat
No instance for (Ord Weekday) arising form a use of '>'
```

• Add deriving (C,C,...,C) to data declaration to define canonical (intuitive) operations:

```
equality (==,/=)
     Eq
     Show
               printing (show)
     0rd
               ordering (<,<=,max)
     Enum
              enumeration ([x..y])
     Bounded | bounds (minBound, maxBound)
data Move = Rock | Paper | Scissor
  deriving (Eq)
data Outcome = Lose | Tie | Win
  deriving (Show)
outcome :: Move -> Move -> Outcome
outcome Rock Scissor = Win
outcome Paper Rock = Win
outcome Scissor Paper= Win
outcome us
                 them
  |us == them = Tie
  |otherwise = Lose
main :: IO ()
main = do
```

operations

Code example 15: RockPaperScissors.hs

• Product, $r = 1, n_1 = 2$ ()

print \$ outcome Paper Scissor

• Sum of Products:

c (class)

```
data Sequence a = S Int [a]
  deriving (Eq, Show)

fromList :: [a] -> Sequence a
fromList xs = S (length xs) xs

(+++) :: Sequence a -> Sequence a -> Sequence a
S lx xs +++ S ly ys = S (lx + ly) (xs ++ ys)

len :: Sequence a -> Int
len (S lx _) = lx

main :: IO ()
main = do
  print $ fromList [0..9]
  print $ len (fromList ['a'..'z'])
```

Code example 16: sequence.hs

```
data List a = Nil
           | Cons a (List a)
 deriving(Show)
toList :: [a] -> List a
toList [] = Nil
toList (x:xs) = Cons x (toList xs)
fromList :: List a -> [a]
fromList Nil = []
formList (Cons x xs) = x:fromList xs
mapList :: (a -> b) -> List a -> List b
mapList f Nil = Nil
mapList f (Cons x xs) = Cons (f x) (mapList f xs)
liftList f = toList . f . fromList
mapList' :: (a -> b) -> List a -> List b
mapList' f xs = liftList (map f) xs
filterList :: (a -> Bool) -> List a -> List a
filterList _ Nil
                                  = Nil
filterList p (Cons x xs) | p x = Cons x (filterList p xs)
                        | otherwise = filterList p xs
filterList' :: (a -> Bool) -> List a -> List a
filterList' p xs = liftList (filter p) xs
main :: IO()
main = do
 print $ mapList (+1) $ toList[1..5]
 print $ formList $ filterList (> 3) $ mapList (+1) $ toList [1..5]
```

```
data Exp a = Lit a
           | Add (Exp a) (Exp a)
           | Sub (Exp a) (Exp a)
           | Mul (Exp a) (Exp a)
  deriving(Show)
ex1 :: Exp Integer
ex1 = Add (Mul (Lit 5) (Lit 8)) (Lit 2)
evaluate :: Num a => Exp a -> a
evaluate (Lit n)
                 = n
evaluate (Add e1 e2) = evaluate e1 + evaluate e2
evaluate (Mul e1 e2) = evaluate e1 * evaluate e2
evaluate (Sub e1 e2) = evaluate e1 - evaluate e2
main :: IO()
main = do
  print $ ex1
  print $ evaluate ex1
```

Code example 18: eval-compile-run.hs

Vorlesung 6

Type Classes

A Type class C defines a family of type signatures ("methods") whichi all *instances* of c must implement:

```
class \mathbf{C} where f_1 :: t_1 f_2 :: t_2 : f_n :: t_n
```

The t_i must mention a For any f_i , the class may provide default definitions (that instances may overwrite).

• Example

```
class Eq a where

(==) :: a -> a -> Bool

(/=) :: a -> a -> Bool

x /= y = not (x == y)

x == y = not (x /= y)
```

Class Constraints

A class constraint e (a => :: t (where t mentions a) says that e has type t only if a is an instance of class C.

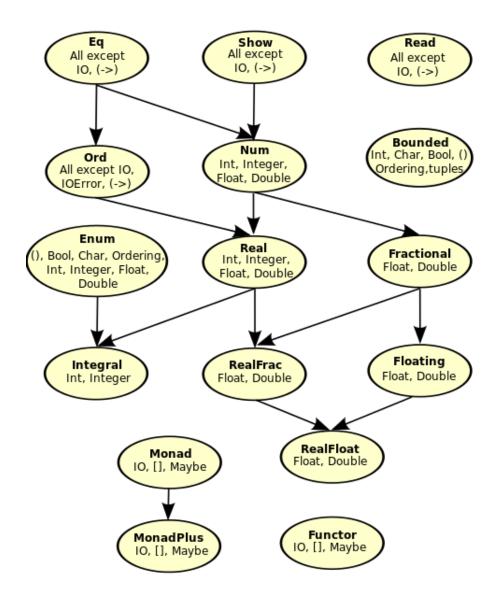

```
:t (+)
(+) :: Num a => a -> a -> a
:t print
print :: Show a => a -> IO ()
:hoogle +Data.List
Data.List sort :: Ord a => [a] -> [a]
:hoogle [(a,b)] -> a -> Maybe b
lookup :: Eq a => a -> a [(a,b)] -> Maybe b
```

Class inheritance

```
Defining class (c_1a, c_2a, ...) \Rightarrow (a where ...) makes type class C a subclass of the c_1 C inherits all methods of the c_i. (a \Rightarrow t implies (c_1a, c_2a, ..., Ca) \Rightarrow t)
```

```
class Enum a where
  succ :: a -> a
  pred :: a -> a
  toEnum :: Int -> a
  fromEnum :: a -> Int
  enumFrom :: a -> [a]
  enumFromThen :: a -> a -> [a]
  enumFromTo :: a -> a -> [a]
  enumFromThenTo :: a -> a -> [a]
  --Minimal complete Definition enumfrom and toEnum
  succ = toEnum . (+1) . fromEnum
  pred = toEnum . (subtract 1) . fromEnum
  enumFrom x = map toEnum [fromEnum x ..]
  enumFromTo x y = map toEnum [fromEnum x .. fromEnum y]
  enumFromThenTo x y z = map toEnum [fromEnum x, fromEnum y .. fromEnum z]
class (Eq a) => Ord a where
  compare
                      :: a -> a -> Ordering
  (<), (<=), (>=), (>) :: a -> a -> Bool
  max, min
                      :: a -> a -> a
  -- Minimal complete Definition compare
 compare x y \mid x == y = EQ
\mid x <= y = LT
              | otherwise = GT
  x \le y = compare x y /= GT
  x < y = compare x y == LT
  x >= y = compare x y /= LT
  x > y = compare x y == GT
class Show a where
  showsPre :: Int -> a -> ShowS
        :: a -> String
  showList :: [a] -> ShowS
  --Minimal complete definition: show or showsPrec
  showsPrec x = show x ++ s
                = showsPrec 0 x ""
  show x
```

Code example 19: Default implementation of Show, Ord and Enum

Class Instances

If type t implements the method of class C, t becomes an *instance* of c:

```
instance C t where f_1 = \langle \operatorname{def} \ \operatorname{of} \ f_1 \rangle \ --\operatorname{all} \ \operatorname{f} \ \operatorname{may} \ \operatorname{be} \vdots \qquad \qquad --\operatorname{provided}, \ \operatorname{minimal} f_n = \langle \operatorname{def} \ \operatorname{of} \ f_n \rangle \ --\operatorname{complete} \ \operatorname{definition} --\operatorname{must} \ \operatorname{be} \ \operatorname{provided}
```

• Example:

 \bullet An instance definition for type constructor t may formulate type constraints for its argument types: a, b \dots :

```
instance (c_1a, c_2, c_3b, \ldots) \Longrightarrow (t a b) where
```

```
:i Enum
class Enum a where
  succ :: a -> a
  pred :: a -> a
  toEnum :: Int -> a
  fromEnum :: a -> Int
  enumFrom :: a -> [a]
  enumFromThen :: a -> a -> [a]
  enumFromTo :: a -> a -> [a]
  enumFromThenTo :: a -> a -> [a]
          -- Defined in 'GHC.Enum'
instance Enum Word -- Defined in 'GHC.Enum'
instance Enum Ordering -- Defined in 'GHC.Enum'
instance Enum Integer -- Defined in 'GHC.Enum'
instance Enum Int -- Defined in 'GHC.Enum'
instance Enum Char -- Defined in 'GHC.Enum'
instance Enum Bool -- Defined in 'GHC.Enum'
instance Enum () -- Defined in 'GHC.Enum'
instance Enum Float -- Defined in 'GHC.Float'
instance Enum Double -- Defined in 'GHC.Float'
fromEnum 'A'
65
fromEnum 'B'
66
toEnum 65
Exception: Prelude. Enum. (). to Enum: bad argument
:t toEnum 65
toEnum 65 :: Enum a => a
toEnum 65 :: Char
'A'
toEnum 0 :: Bool
False
toEnum 20 :: Double
20.0
```

Deriving Class Instances

```
• Automatically made user-defined data (data ...) intsances of classes c_i \in \{ \mathsf{Eq, Ord, Enum, Bounded, Show, Read} \} data T a_1 a_2 ... a_n = ... deriving (c_1 \ldots, c_n) import Data.Maybe import Data.Tuple data Outcome = Lose | Tie | Win
```

```
deriving(Eq,Ord,Enum,Bounded,Show)
data Move = Rock | Paper | Scissor
 deriving (Eq)
instance Ord Move where
 Rock <= Rock = True
 Rock <= Paper = True
Paper <= Paper = True
 Paper <= Scissor = True
 Scissor <= Scissor= True
 Scissor <= Rock = True
  <= = False
instance Show Move where
 show Scissor = ""
 show Rock = ""
 show Paper = ""
table :: [(Move,Int)]
table = [(Rock, 0), (Paper, 1), (Scissor, 2)]
instance Enum Move where
 fromEnum o = fromJust $ lookup o table
 toEnum n = fromJust $ lookup n $ map swap table
outcome :: Move -> Move -> Outcome
outcome Paper Rock
                     = Win
outcome Scissor Paper = Win
outcome us them
 |us == them = Tie
  |otherwise = Lose
main :: IO ()
main = do
 print $ outcome Paper Scissor
```

```
import Data. Maybe
import Data. Tuple
data Outcome = Lose | Tie | Win
instance Eq Outcome where
  Lose== Lose= True
  Tie == Tie = True
 Win == Win = True
  _ == _ = False
instance Enum Outcome where
  fromEnum Lose = 0
  fromEnum Tie = 1
  fromEnum\ Win = 2
  toEnum ⊙ = Lose
 toEnum 1 = Tie
toEnum 2 = Win
instance Show Outcome where
  show Lose = "Lose"
  show Tie = "Tie"
  show Win = "Win"
instance Ord Outcome where
  Lose <= Lose = True
  Lose <= Tie = True
  Lose <= Win = True
  Tie <= Tie = True
 Tie <= Win = True
 Win <= Win = True
  _ <= _ = False
data Move = Rock | Paper | Scissor
instance Eq Move where
  Rock == Rock = True
  Paper == Paper = True
  Scissor == Scissor = True
        ==
               _ = False
table :: [(Move,Int)]
table = [(Rock, 0), (Paper, 1), (Scissor, 2)]
instance Enum Move where
  fromEnum o = fromJust $ lookup o table
  toEnum n = fromJust $ lookup n $ map swap table
outcome :: Move -> Move -> Outcome
outcome Rock     Scissor = Win
outcome Paper Rock = Win
outcome Scissor Paper
                      = Win
outcome us
               them
  |us == them = Tie
  |otherwise = Lose
main :: IO ()
main = do
  print $ outcome Paper Scissor
```

Vorlesung 7

Domain Specific Languages

• "small languages" designed to easily and directly express the concepts/idioms of a given domain. *Not* Turing-complete in general.

		Domain	DSL
•	Examples:	Os automation	Shell scripts
		Typesetting	T_EX , IAT_EX
		Queries	SQL
		Game Scripting	UnrealScript, Lua
		Parsing	Bison, ANTLR

- Functional Languages are good hosts for Embedded DSLs:
 - algebraic data types (e.g model abstract syntax trees)
 - higher-order functions (e.g control constructs)
 - lightweight syntax (layout/whitespace, non-alphabetic identifiers)

Example: An embedded DSL for finite sets of integers:

```
type IntegerSet = ...
empty :: IntegerSet
insert :: Integer    -> IntegerSet -> IntegerSet
delete :: Integer    -> IntegerSet -> IntegerSet
member :: Integer    -> IntegerSet -> Bool
member 3 (insert 1 (delete 3 (insert 2 (insert 3 empty))))
→ False
```

DSL: (1) Library of functions, implementaion details exposed

Modules

Group related definitions (names, types) in a single file (named M.hs)

```
module M where
type Predicate a = a -> Bool
id :: a -> a
id = \x -> x
```

Hierarchy: module A.B.C.M in file A/B/C/M.hs

• definitions in other module M:

```
import M
```

• Explicit export Lists hode all other definitions

```
module M (id) where ...
--type Predicate a not exported
```

```
import Data.List (nub)
type IntegerSet = [Integer]
s1,s2 :: IntegerSet
s1 = insert 1 (insert 2 (insert 3 empty))
s2 = foldr insert empty [1..10]
empty :: IntegerSet
empty = []
insert :: Integer -> IntegerSet -> IntegerSet
insert x xs = x:xs
delete :: Integer -> IntegerSet -> IntegerSet
delete x xs = filter (/= x) xs
() :: Integer -> IntegerSet -> Bool
x \mid xs = elem \times xs
() :: IntegerSet -> IntegerSet -> Bool
xs \mid ys = all (\x -> x \mid ys) xs
card :: IntegerSet -> Int
card xs = length (nub xs)
main :: IO ()
main = print $ 1 | s2
```

Code example 21: library-exposed.hs

 Abstract data types: export algebraic datatypes, but not its constructor functions

```
module M (Rose, leaf) where
data Rose a = Node a [Rose a] --constructor Node not exported
leaf :: a -> Rose a
leaf x = Node x []
```

• Export constructors:

```
module M (Rose (Node), leaf) where ... module M (Rose (...), leaf) where ...
```

• Qualified imports to partition space:

```
import qualified M [as Nickname]
t :: M.Rose Char
t = M.leaf 'x'
```

```
:t fromJust
Not in scope: 'fromJust'
import Data.Maybe
:t fromJust
fromJust :: Maybe a -> a

import qualified Data.Maybe
:t Data.Maybe.fromJust
Data.Maybe.fromJust :: Maybe a -> a

import qualified Data.Maybe as DM
:t DM.fromJust
DM.fromJust :: Maybe a -> a
```

• Partially import module:

```
import Data.List (nub,maybe)
import Prelude hiding (otherwise)
otherwise :: Bool
otherwise = False
```

```
module SetLanguage
    (IntegerSet,
    empty,
    insert,
    delete,
    member
    ) where
data IntegerSet = IS [Integer]
empty :: IntegerSet
empty = IS []
insert :: IntegerSet -> Integer -> IntegerSet
insert (IS xs) x = IS (x:xs)
delete :: IntegerSet -> Integer -> IntegerSet
delete (IS xs) x = IS (filter (/= x) xs)
member :: IntegerSet -> Integer -> Bool
member (IS xs) x = elem x xs
module SetLanguage
    (IntegerSet,
    empty,
    insert.
    delete.
    member
    ) where
data IntegerSet = IS (Integer -> Bool)
empty :: IntegerSet
empty = IS (\_ -> False)
insert :: IntegerSet -> Integer -> IntegerSet
insert (IS f) x = IS (\langle y \rangle - \rangle x == y \mid | f y)
delete :: IntegerSet -> Integer -> IntegerSet
delete (IS f) x = IS (y \rightarrow y /= x \& f y)
member :: IntegerSet -> Integer -> Bool
member (IS f) x = f x
```

Code example 22: Two implementations of the SetLanguage module

Vorlesung 8

- Shallow DSL embedding: Semantiics of DSL operations directly expressed in terms of a host language value (e.g list or characteristic function).
 - constructors $(\mbox{empty}\,,\mbox{insert}\,,\mbox{delete})$ perform the work, harder to add
 - Observer (member) trivial
- Deep DSL embedding: DSL operations build an abstract syntax Tree (AST) that represents applications and arguments
 - constructors merely build the AST, very easy to add
 - observer: interpret (traverse) the AST and perform the work

```
module SetLanguageDeep(IntegerSet(Empty,Insert,Delete),
    member, card) where
data IntegerSet = Empty
                  | Insert IntegerSet Integer
                  | Delete IntegerSet Integer
  deriving (Show)
member :: IntegerSet -> Integer -> Bool
                   _ = False
member Empty
member (Insert xs x) y = x == y \mid \mid member xs y
member (Delete xs x) y = x /=y \&\& member xs y
card :: IntegerSet -> Integer
card Empty
                                  = 0
card (Insert xs x) \mid member xs x = card xs
                   | otherwise
                                = card xs + 1
card (Delete xs x) | member xs x = card xs - 1
                   | otherwise
                               = card xs
```

Code example 23: SetLanguageDeep.hs

```
:i Num
class Num a where

                       Right b -> if b then eval e1 else eval e2
```

Code example 25: ExprDeepNum.hs

Generalized Algebraic Datatypes

Idea:

- Encode the type of a DSL expression (here : Integer or Bool) in its ${\it Haskell type}$
- Use Haskell's type checker to ensure at *compile time* that only well-typed DSL expressions are built:

GADTs

- Language extensions: {-## LANGUAGE GADTs ##-}
- Define entirely new parameters Type T, its (value) constructors k_i and their type signatures

```
data T a_1 \ a_2 \ \dots \ a_n where k_1 \ \colon \colon b_{11} \ -> \ \dots \ b_{1n_1} \ -> \ \mathsf{T} \ t_{11} \ t_{12} \dots \ t_{1n} \ k_2 \ \colon \colon b_{21} \ -> \ \dots \ b_{2n_2} \ -> \ \mathsf{T} \ t_{21} \ t_{22} \dots \ t_{2n}
```

```
{-# LANGUAGE GADTs #-}
module ExprDeep
    (Expr(..),
    eval
    ) where
data Expr a where
  ValI :: Integer
                                            -> Expr Integer
  ValB :: Bool
                                            -> Expr Bool
  Add :: Expr Integer -> Expr Integer -> Expr Integer
         :: Expr Bool -> Expr Bool -> Expr Bool
:: Expr Integer -> Expr Bool
   EqZero :: Expr Integer
         :: Expr Bool -> Expr a -> Expr a -> Expr a
instance Show (Expr a) where
  show (ValI n) = show n
  show (ValB b) = show b
  show (Add e1 e2) = show e1 ++ " + " ++ show e2
  show (And e1 e2) = show e1 ++ \Delta ++ show e2
  show (EqZero e) = show e ++ "== 0"
  show (If p e1 e2) = "if " ++ show p ++ " then " ++ show e1 ++ " else " ++ show
eval :: Expr a -> a
eval (ValI n) = n
eval (ValB b) = b
eval (Add e1 e2) = eval e1 + eval e2
eval (And e1 e2) = eval e1 && eval e2
eval (EqZero e) = eval e == 0
eval (If p e1 e2) = if eval p then eval e1 else eval e2
```

    rewrite (Let v e1 (Val v'))
                                   | v == show v' = rewrite e1
                                             = Let v (rewrite e1) (rewrite e2)
    rewrite (Let v e1 e2 )
    rewrite e
                                               = e
main :: IO()
main = print (prog :: String)
```

Code example 28: expr-embeddings.hs

Shallow Embedding of a String Matching DSL

- Pattern:
 - 1. Given a string, a pattern returns a *list of matches*. Match failure? Replace failure return the *empty list* (of matches) by a list of suc-
 - 2. A match consists of a value (e.g the match of characters, tokens parse tree) and the residual string to match

Thus: type Pattern a = String -> [(a, String)]

A pattern of things is list of things and strings

Torsten Grust, 10.12.2015

cesses

• DSL design:

```
Pattern DSL Function Char -> String ([Char,String])

match literal match empty string fail always alternative sequence repetition

DSL Function Char -> String ([Char,String])

lit :: Char -> Pattern Char

empty :: a -> Pattern a

fail :: Pattern a

-> Pattern a -> Pattern a

seq :: (a -> b -> c) -> Pattern a -> Pattern b -> Pattern c
```

```
module PatternMatching (Pattern,
                        module Prelude,
                        lit, empty, fail,
                        alt, seq, rep, rep1,
                        alts, seqs, lits, app) where
                 Prelude hiding (fail, seq)
import
-- Given a string, a pattern returns the (possibly empty) list of
-- possible matches. A match consists of a match value (e.g., matched
-- the matched character(s), token, or parse tree) and the residual string
-- left to match:
type Pattern a = String -> [(a, String)]
-- BASIC PATTERNS
-- match character c, returning the matched character
lit :: Char -> Pattern Char
lit c []
lit c (x:xs) | c == x = [(c, xs)]
              | otherwise = []
-- match the empty string, return v
empty :: a -> Pattern a
empty v xs = [(v, xs)]
-- fail always (yields empty list of matches)
fail :: Pattern a
fail _ = []
-- COMBINE PATTERNS
-- match p or q
alt :: Pattern a -> Pattern a -> Pattern a
alt p q xs = p xs ++ q xs
-- match p and q in sequence (use f to combine match values)
seq :: (a -> b -> c) -> Pattern a -> Pattern b -> Pattern c
seq f p q xs = concat (map (\((v1, xs1) ->
                         map (\(v2, xs2) -> (f v1 v2, xs2))
                             (q xs1))
                         (p xs)
-- An alternative (more consise and readable) implementation of seq
-- based on list comprehension syntax:
-- seq f p q xs = [ (f v1 v2, xs2) | (v1, xs1) <- p xs, (v2, xs2) <- q xs1 ]
-- match p repeatedly (including 0 times)
rep :: Pattern a -> Pattern [a]
rep p = alt (seq (:) p (rep p)) (empty [])
-- match p repeatedly, but at least once
rep1 :: Pattern a -> Pattern [a]
```

rep1 p = seq (:) p (rep p)

```
import
                 Prelude

import
                 PatternMatching
-- Make use of the fact that the pattern matching DSL is *embedded*
-- into Haskell: define new functions (abstractions) that combine
-- simple patterns
-- Example:
-- Match a fully parenthesized arithmetic expression over integers,
-- e.g. ((4*10)+2)
-- Variant 1: return list of matched characters
digit :: Pattern Char
digit = alts [ lit d | d <- ['0'..'9'] ]
number :: Pattern String
number = rep1 digit
op :: Pattern String
op = alts [ lits o | o <- ["+", "-", "*", "/"] ]
expr :: Pattern String
expr = alts [ number, app concat (seqs [lits "(", expr, op, expr, lits ")"]) ]
-- Variant 2: return a simple AST for the matched expression
data Expr a =
    Num a
  | Op (Expr a) String (Expr a)
  deriving (Show)
number' :: Pattern (Expr Integer)
number' = app (Num . read) (rep1 digit)
expr' :: Pattern (Expr Integer)
expr' = alts [ number', seq (\_ (e1,(o,(e2,\_))) -> 0p e1 o e2)
                            (lit '(') (seq (,)
                                      expr' (seq (,)
                                            op (seq (,)
                                               expr' (lit ')')))
             ]
main :: IO ()
main = do
  print $ rep1 digit "1234.56"
  print $ lits "abc" "abcdef"
```

print \$ expr "((4*10)+2)"

Vorlesung 10

Lazy Evaluation

To execute a programm, Haskell *reduces* expression to values. Haskell uses *normal order reduction* to select the next expression to reduce:

- The *outermost* reducable expression (redex) is reduced first.
- \Rightarrow Function application are reduced first before their arguments.
- If no further redex is found, the expression is in *normal form*. and reduction terminates.

```
fst :: (a,b) -> a
fst(x,y) = x
sqr :: Num a => a -> a
sqr x = x * x
______
fst (sqr (1 + 3), sqr (1 + 3))
                        \rightarrow (1 + 3) * (1 + 3) [sqr]
                        → 4 * 4
                                              [+/+]
(define-racket-procedures pair
 make-pair
 pair?
  (pair-fst)
  (pair-snd))
(define fst
  (lambda (p)
    (pair-fst p)))
(define sqr
  (lambda (x) (* x x)))
;Racket uses applicative order reduction (innermost first)
```

Haskell avoids the duplication of work through *graph reduction*: Expression are shared (referenced more than once) instead of duplicated. Reduction of sqr(1 + 3):

Lazy evaluation: normal order reduction + sharing + WHNF thunks

Code example 29: This Programm compiles in Haskell, but not in Racket

WHNF

An expression e ist in weak head normal form (WHNF) if it is of the following form:

```
① \mathbf{V} (where \mathbf{V} is an \mathit{atomic} value <code>Integer</code>, <code>Char</code>, <code>Bool</code>,...)
```

- ② $c e_1 e_2 \dots e_n$ (where c is an n-ary constructor (like (:)))
- ③ $f e_1 e_2 \dots e_m$ (where f is a n-ary function, m < n)

Haskell reduces values to WHNF only (stop criteria for reducion) unless we request reduction to normal fprm (e.g when printing result)

Example expressions in WHNF

```
42 -- ①
(sqr 2,sqr 4) -- ②
f x = map f xs -- ② (:)
Just (40 + 2) -- ② Just
(* (40 + 2)) -- ③ * binary
(\x -> 40 + 2) -- ③ * binary

(1 + 3) : []
[4]
it :: [Integer]
let xs = (1 + 3) : []
xs :: [Integer]
:sprint xs
xs = [_]
```

Lazy Evaluation and Bottom (\bot)

Some Haskell expressions have the value $bottom\ (perp)$ Examples: error "..", undefined, bomb. Lazy evaluation admits functions that return a non-bottom value even if they receive \bot as an argument (also:non-Strict functions). N-ary function is strict in its i-th argument, if $f\ x_1\ ...\ x_{i-1}\ \bot\ x_{i+1}\ ...\ x_n = \bot$ Examples:

```
const :: a -> b -> a strict in first, non-strict in second argument
(&&) :: Bool -> Bool -> Bool
```

 Δ If a function pattern matches an argument, Haskell semantics define it to be strict in that argument. Example:

```
data T = T Int
f :: T -> Int
f(T x) = 42

ightarrow undefined
f undefined
f (T undefined) \rightarrow 42
min [8,6,1,7,5] \rightarrow (head . isort (<)) [8,6,1,7,5]
                                                            [min]
\rightarrow head (isort (<) [8,6,1,7,5])
                                                             [(.)]
\rightarrow head (ins 8 (ins 6 (ins 1 (ins 7 (ins 5 []))))) [isort.2*]
\rightarrow head (ins 8 (ins 6 (ins 1(ins 7 [8]))))
                                                             [ins.1]
\rightarrow head (ins 8 (ins 6 (ins 1 (5 : ins 7 []))))
                                                             [ins.3]
\rightarrow head (ins 8 (1 : ins 6 ( 5 : ins 7 [])))
                                                             [ins.2]
\rightarrow (1 : ins 8 (ins 6 (5 : ins 7 [])))
                                                             [ins.3]
\rightarrow 1
min [1..1000000]
1
it :: Integer
(1.50 secs, 521,738,256 bytes)
min [1..10000000]
1
it :: Integer
(15.43 secs, 5,164,721,896 bytes)
```

```
import

 print $ f a
 print $ g undefined
 print $ g b
                 Code example 30: Bottom type
import
                 Prelude hiding (min)
min :: Ord a => [a] -> a
min = head . isort (<)</pre>
isort :: Ord a => (a -> a -> Bool) -> [a] -> [a]
isort (<<<) [] = []
                                                 --[isort.1]
isort (<<<) (x:xs) = ins x (isort (<<<) xs) --[isort.2]
  where
                       = [x]
                                                 --[isort.1]
    ins x []
                      | x <<< y = x:y:ys --[isort.2]
    ins x (y:ys)
                      | otherwise = y:ins x ys --[isort.3]
main :: IO ()
main = do
 print $ isort (<) [8,6,1,7,5]</pre>
  print $ min [8,6,1,7]
```

Code example 31: Finding the minimum by sorting the list

Vorlesung 11

Infinite Lists (Data Structures)

One consequence of lazy evaluation, programs can handle *infinite Lists* as long as any run will inspect onlt a finite prefix of such a list. Enables a modular programming style:

- generator functions produce an infinite number of solutions/approximations
- 2. **test functions** select one (or finite number of) solutions from this infinie list)

Example: Newton-Raphson square root approximation Iteratively approximate the square root of \boldsymbol{x}

```
1. a_0 = x/2
  2. a_{i+1} = \frac{(a_i + x/a_i)}{2}
                                              a = (a + x/a/2) \Leftrightarrow a = \sqrt{x}
import
                    Prelude hiding (iterate)
iterate :: (a -> a) -> a -> [a]
iterate f x = x: iterate f (f x)
within :: (Ord a, Num a) \Rightarrow a \rightarrow [a] \rightarrow a
within eps (x1:x2:xs) | abs (x1 - x2) \le eps = x2
                          | otherwise
                                           = within eps (x2:xs)
sgroot :: Double -> Double -> Double
sqroot eps x = within eps (iterate next a0)
  where
    a0 = x / 2
    next a = (a + x/a)/2
main :: IO ()
main = print $ sqroot 0.0001 9
```

Example (Tic-Tac-Toe game tree):

Build the (potentially huge) tree of possible moevs for the Tic-Tac-Toe Board game. Evaluate promise of game position.

Plan:

(I) Find representation of game position (board + player next up)

1	2	3
4	5	6
X	О	X

```
(2) provide pretty-printing for game
 (3) Define initial position and possible moves: moves :: Position -> [Position]
 (4) Evaluate a given position: static :: Position -> Int
import
                 Data.List
                                          (intersperse, transpose)
import
                 Text.PrettyPrint.Boxes
data Player = X | 0
 deriving (Eq, Show)
type Square = Either Int Player
type Board = [[Square]]
data Position = Position Board Player
showSquare :: Board -> [String]
showSquare = either show show
showBoard = frame "" ""
            map (concat . frame "|" "|" . map showSquare)
  where
    frame l m r xs = [l] ++ intersperse m xs ++ [r]
instance Show Position where
  show (Position b ) = unlines (showBoard b)
moves :: Position -> [Position]
moves pos@(Position b ) = map (move pos) (openSquares b)
  where
    openSquares b = [Left sq | Left sq <- concat b]</pre>
    move (Position b p) sq = Position (map (map (place sq p)) b) (next p)
    place sq p sq' | sq == sq' = Right p
    place _ _ sq' = sq'
    next X = 0
    next 0 = X
static :: Position -> Int
static (Position b p) = if won b then case p of
                                     X -> -1
                                     0 -> 1
                         else 0
  where
    won b = any full (diagonals b ++ rows b ++ cols b)
    full [Right p1, Right p2, Right p3] = p1 == p2 && p2 == p3
    full = False
    diagonals [[a1, ,a3],[ ,b2, ],[c1, ,c3]] = [[a1,b2,c3],[a3,b2,c1]]
```

```
rows = id
cols = transpose

main :: IO ()
main = putStrLn "Hello World"
```
